

1. Which are the top three variables in your model which contribute most towards the probability of a lead getting converted?

**Answer:**

The features used to build the model have been represented below based on their importance in lead conversion **as per their coefficient values**.

As per the above diagram, **the top 3 variables that contribute most towards the probability of a lead getting converted are:**

- ✓ **Occupation**
- ✓ **Lead Origin**
- ✓ **Lead Source**

2. What are the top 3 categorical/dummy variables in the model which should be focused the most on in order to increase the probability of lead conversion?

**Answer:**

As per the above diagram, the top 3 categorical/dummy variables that contribute the most towards the probability of a lead getting converted are also:

- ✓ **Occupation\_Working Professional**
- ✓ **Lead Origin\_Lead Add Form**
- ✓ **Lead Source\_Welingak Website**

3. X Education has a period of 2 months every year during which they hire some interns. The sales team has around 10 interns allotted to them. So, during this phase, they wish to make the lead conversion more aggressive. So, they want almost all of the potential leads (i.e. the customers who have been predicted as 1 by the model) to be converted and hence, want to make phone calls to as much of such people as possible. Suggest a good strategy they should employ at this stage.

**Answer:**

**Sensitivity/Recall** with respect to our model can be defined as the ratio of **total number of actual Conversions correctly predicted to the total no of actual Conversions**.

Similarly, **Specificity** can be defined as the ratio of **total no of actual non-Conversions correctly predicted to the total number of actual non-Conversions**.

For a model, as one increases, the other decreases and vice versa.

Different values of the sensitivity and specificity can be achieved for the same model by changing the Conversion Probability cutoff threshold value.

For our model, the below graph shows how the Sensitivity and Specificity rating changes with change in the threshold value:

When the **probability thresholds are very low, the sensitivity is very high, and specificity is very low.** Similarly, for larger probability thresholds, the sensitivity values are very low, but the specificity values are very high.

High sensitivity implies that our model will correctly identify almost all leads who are likely to Convert. It will do that by over-estimating the Conversion likelihood, i.e. it will misclassify some non-Conversion cases as Conversions (this is fine and that will be taken care in later stages by X Education).

Now, since X Education has more man-power for these 2 months and they wish to make the lead conversion more aggressive by wanting almost all the potential leads, we can **choose a lower threshold** value for Conversion Probability.

This will **ensure the Sensitivity rating is very high which in turn will make sure almost all leads who are likely to Convert are identified correctly** and the agents can make phone calls to as much of such people as possible.

Based on the lead score that we have assigned; X Education can make phone calls to the customer who have **lead score in range between 40% to 100%.**

4. Similarly, at times, the company reaches its target for a quarter before the deadline. During this time, the company wants the sales team to focus on some new work as well. So, during this time, the company's aim is to not make phone calls unless it's extremely necessary, i.e. they want to minimize the rate of useless phone calls. Suggest a strategy they should employ at this stage.

**Answer:**

Following the similar logic as above and context from the previous question, **High Specificity implies that our model will correctly identify almost all leads who are not likely to Convert.** It will misclassify some non-Conversion cases as Conversions.

Therefore, since X Education has already reached its target for a quarter and doesn't want to make phone calls unless it's extremely necessary, i.e. they want to minimize the rate of useless phone calls, **we can choose a higher threshold value for Conversion Probability.**

**This will ensure the Specificity rating is very high**, which in turn will make sure almost all leads to be identified properly who are mostly being not converted. As a result, the agents won't have to make unnecessary phone calls and can focus on some other work.

Based on the lead score that we have assigned; X Education can make phone calls to the customer who have **lead score in range between 85% to 100%.**
